

Building and Deploying Raspberry PI Kernel

This tutorial shows how to build a Raspberry PI kernel and install it on the device. As building the kernel on Raspberry PI itself could take several days due to a relatively slow CPU, we will be using an additional Linux machine to build it.

1. Raspberry PI kernel is stored in a Git repository and requires installing a Git client to fetch the files. Install the client on your build machine. E.g. on Debian-based systems it can be done by running the following command:
`sudo apt-get install git`
2. Create a directory to store Raspberry-related files (e.g. `/home/<username>/raspberrypi`) and run the following command in that directory:
`git clone https://github.com/raspberrypi/linux.git`
The Raspberry PI kernel source will be downloaded to the 'linux' subdirectory (1.5-2 GB):

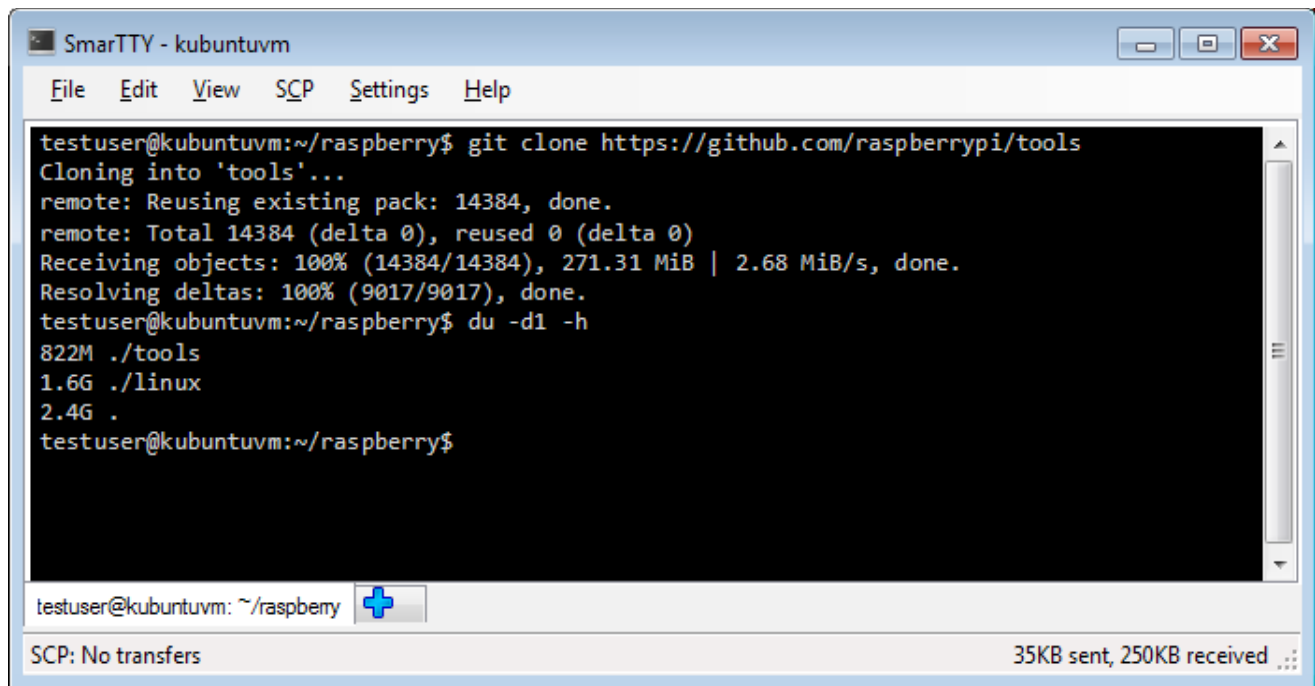

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

testuser@kubuntuvvm:~/raspberrypi$ git clone https://github.com/raspberrypi/linux.git
Cloning into 'linux'...
remote: Counting objects: 3398084, done.
remote: Compressing objects: 100% (565673/565673), done.
remote: Total 3398084 (delta 2803844), reused 3397329 (delta 2803277)
Receiving objects: 100% (3398084/3398084), 922.20 MiB | 2.89 MiB/s, done.
Resolving deltas: 100% (2803844/2803844), done.
testuser@kubuntuvvm:~/raspberrypi$

testuser@kubuntuvvm: ~/raspberrypi
SCP: No transfers 14KB sent, 121KB received
```

3. Download Raspberry PI cross-compilers by running the following command on your build machine:
`git clone https://github.com/raspberrypi/tools`
The tools will be unpacked into the 'tools' subdirectory and will occupy ~1GB of space:

The screenshot shows a terminal window titled "SmarTTY - kubuntuvvm". The terminal output is as follows:

```
testuser@kubuntuvvm:~/raspberrypi$ git clone https://github.com/raspberrypi/tools
Cloning into 'tools'...
remote: Reusing existing pack: 14384, done.
remote: Total 14384 (delta 0), reused 0 (delta 0)
Receiving objects: 100% (14384/14384), 271.31 MiB | 2.68 MiB/s, done.
Resolving deltas: 100% (9017/9017), done.
testuser@kubuntuvvm:~/raspberrypi$ du -d1 -h
822M ./tools
1.6G ./linux
2.4G .
testuser@kubuntuvvm:~/raspberrypi$
```

At the bottom of the terminal window, there is a status bar showing "SCP: No transfers" and "35KB sent, 250KB received".

4. The Raspberry PI tools directory contains several toolchain versions:

- tools/arm-bcm2708/arm-bcm2708hardfp-linux-gnueabi
- tools/arm-bcm2708/arm-bcm2708-linux-gnueabi
- tools/arm-bcm2708/gcc-linaro-arm-linux-gnueabihf-raspbian

The last one is the toolchain containing the linaro patches, so we will use it for cross-compilation. Set the CCPREFIX environment variable to the prefix of the third toolchain and test it by invoking GCC using the prefix, e.g.:

```
export CCPREFIX=/home/testuser/raspberrypi/tools/arm-bcm2708/gcc-linaro-arm-linux-gnueabihf-raspbian/bin/arm-linux-gnueabihf- ${CCPREFIX}gcc -v
```

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

testuser@kubuntuvm:~/raspberrypi/tools/arm-bcm2708$ export CCPREFIX=/home/testuser/raspberrypi/
tools/arm-bcm2708/gcc-linaro-arm-linux-gnueabihf-raspbian/bin/arm-linux-gnueabihf-
testuser@kubuntuvm:~/raspberrypi/tools/arm-bcm2708$ ${CCPREFIX}gcc -v
Using built-in specs.
COLLECT_GCC=/home/testuser/raspberrypi/tools/arm-bcm2708/gcc-linaro-arm-linux-gnueabihf-raspbian/bin/arm-linux-gnueabihf-gcc
COLLECT_LTO_WRAPPER=/home/testuser/raspberrypi/tools/arm-bcm2708/gcc-linaro-arm-linux-gnueabihf-raspbian/bin/./libexec/gcc/arm-linux-gnueabihf/4.8.3/lto-wrapper

testuser@kubuntuvm:~/raspberrypi/tools/arm-bcm2708$ _
```

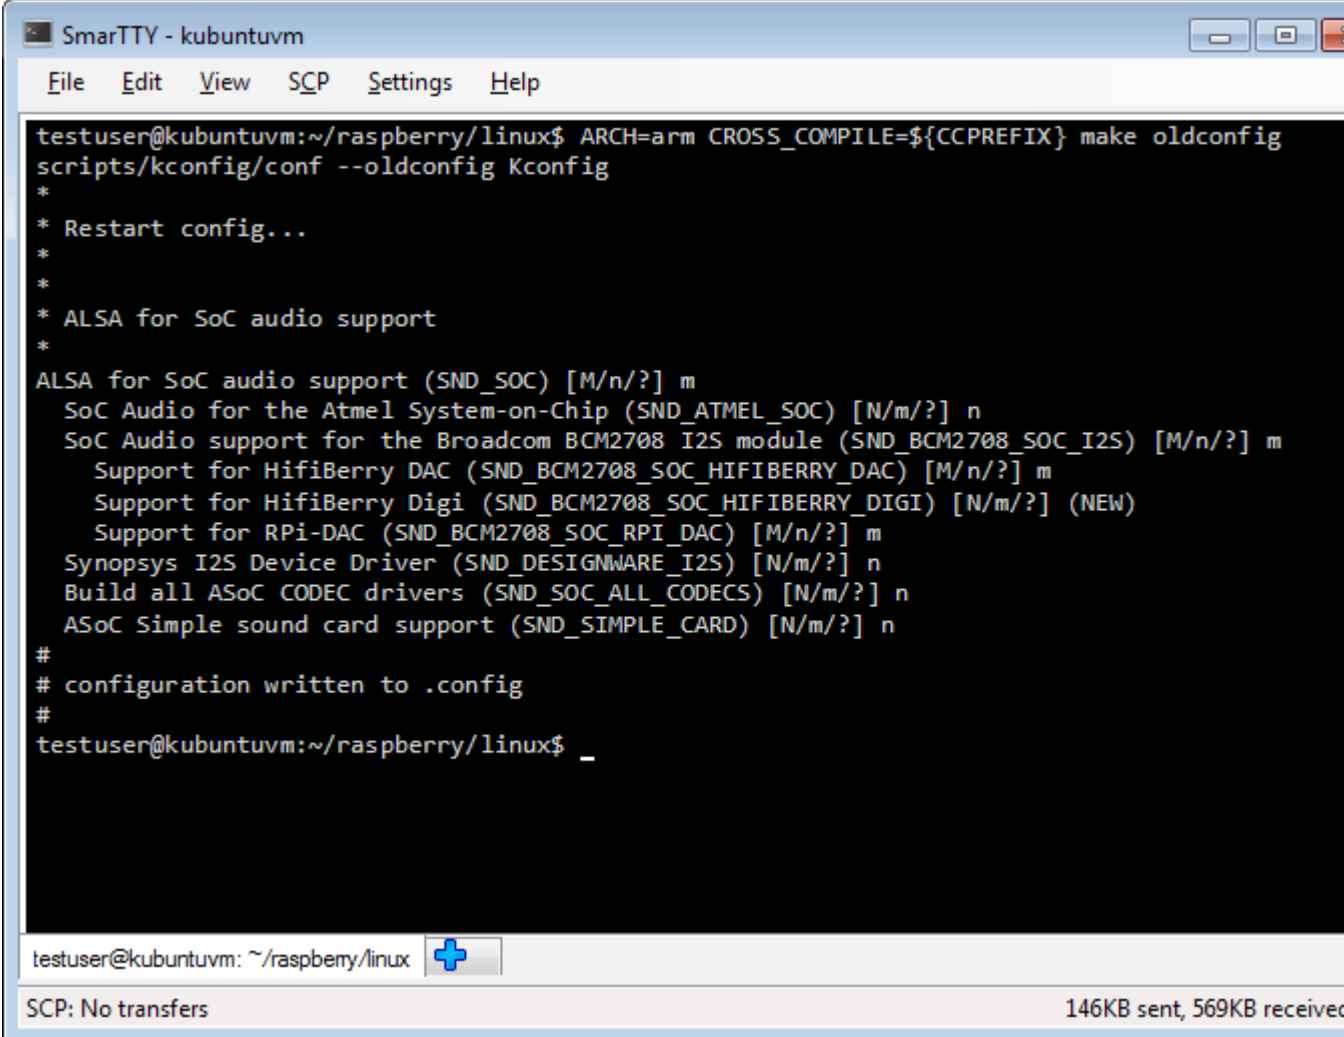

testuser@kubuntuvm: ~/raspberrypi/tools/arm-bcm2708

SCP: No transfers 98KB sent, 338KB received

5. Before we can build the kernel we need to configure it. A very good starting point would be the configuration file from your existing Raspberry PI that can be obtained by reading and unpacking the **/proc/config.gz** file on Raspberry PI. Go to the 'linux' subdirectory with the downloaded kernel sources and run the following commands there (assuming 'raspberrypi' is the host name of your Raspberry PI):
scp pi@raspberrypi:/proc/config.gz .
gunzip -c config.gz > .config
If the config.gz file is missing, run the following command to load the module that provides it:
sudo modprobe configs
6. Run the following command in the Linux kernel source directory to bootstrap the new kernel configuration from the **.config** file obtained from Raspberry PI. Note that if you used an old SD card image, you will get a lot of questions on recently added features not mentioned in

the old config file:

ARCH=arm CROSS_COMPILE=\${CCPREFIX} make oldconfig

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

testuser@kubuntuvm:~/raspberrylinux$ ARCH=arm CROSS_COMPILE=${CCPREFIX} make oldconfig
scripts/kconfig/conf --oldconfig Kconfig
*
* Restart config...
*
*
* ALSA for SoC audio support
*

#
# configuration written to .config
#
testuser@kubuntuvm:~/raspberrylinux$ _
```

testuser@kubuntuvm: ~/raspberrylinux

SCP: No transfers 146KB sent, 569KB received

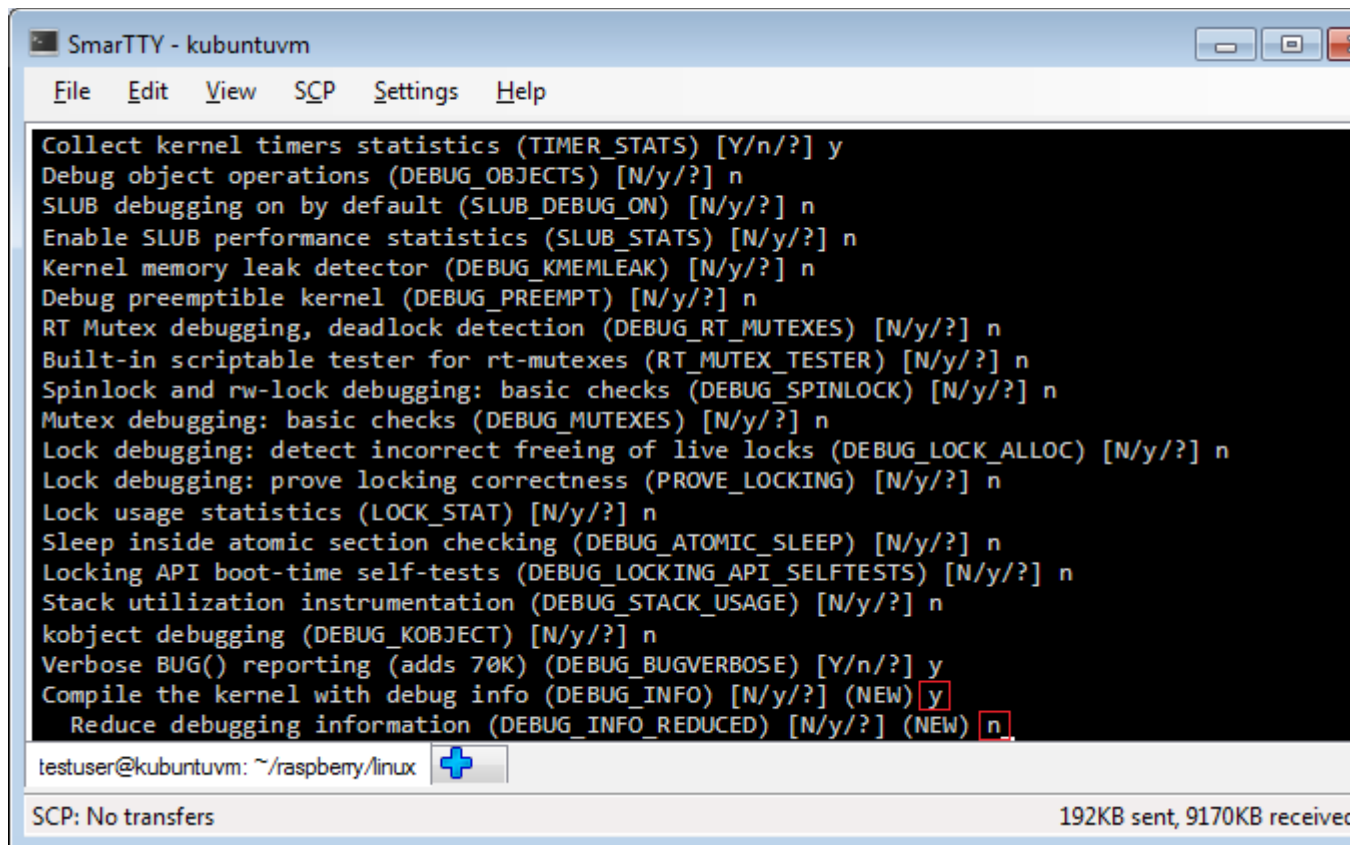

Do not forget to specify ARCH. Otherwise the kernel will be configured using x86 configuration options and will be missing ARM ones leading to a build failure.

7. Now reset all previous options related to debug symbols and enable them explicitly:

8. `grep -v DEBUG_INFO < .config > newconfig`

`mv newconfig .config ARCH=arm`

`CROSS_COMPILE=${CCPREFIX} make oldconfig`

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

Collect kernel timers statistics (TIMER_STATS) [Y/n/?] y

testuser@kubuntuvvm: ~/raspberry/linux
SCP: No transfers 192KB sent, 9170KB received
```

Enable the 'DEBUG_INFO' option and don't enable the DEBUG_INFO_REDUCED option.

9. Now it's time to build the kernel. Run the following command:

```
ARCH=arm CROSS_COMPILE=${CCPREFIX} make
```

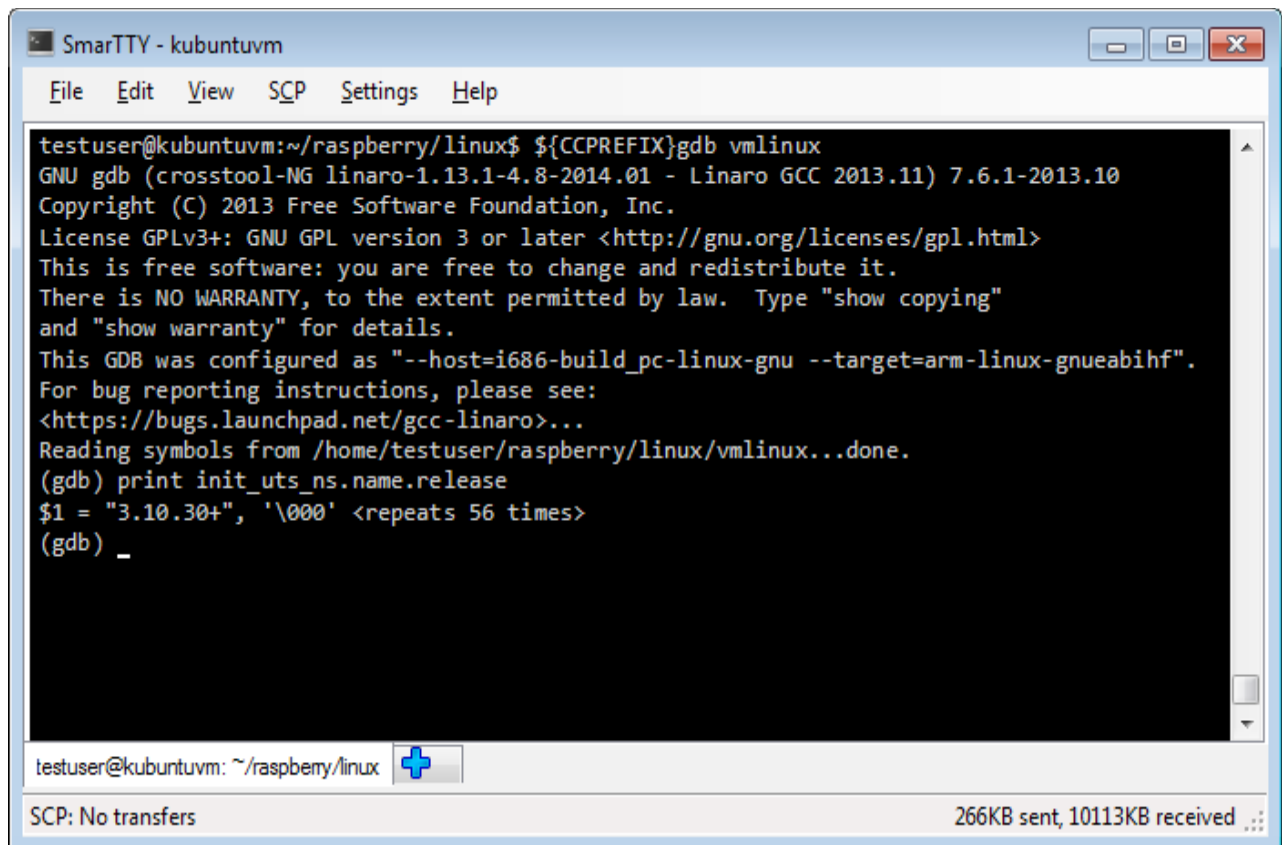

Building the kernel can take several hours and can be sped up by adding a '-j<amount of cores>' on a multi-core machine to parallelize the build.

10. Once the kernel build is complete we need to verify that it contains the symbols. Open the kernel image using the gdb from the cross-toolchain and look at the value of

init_uts_ns.name.release:

```
${CCPREFIX}gdb vmlinux
```

```
print init_uts_ns.name.release
```

A screenshot of a SmarTTY terminal window titled "SmarTTY - kubuntuvvm". The window has a menu bar with "File", "Edit", "View", "SCP", "Settings", and "Help". The terminal content shows a user running GDB on vmlinux. The output includes GDB version information, copyright notice, license information, and the result of the command "print init_uts_ns.name.release", which is "3.10.30+", repeated 56 times. The status bar at the bottom shows "SCP: No transfers" and "266KB sent, 10113KB received".

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

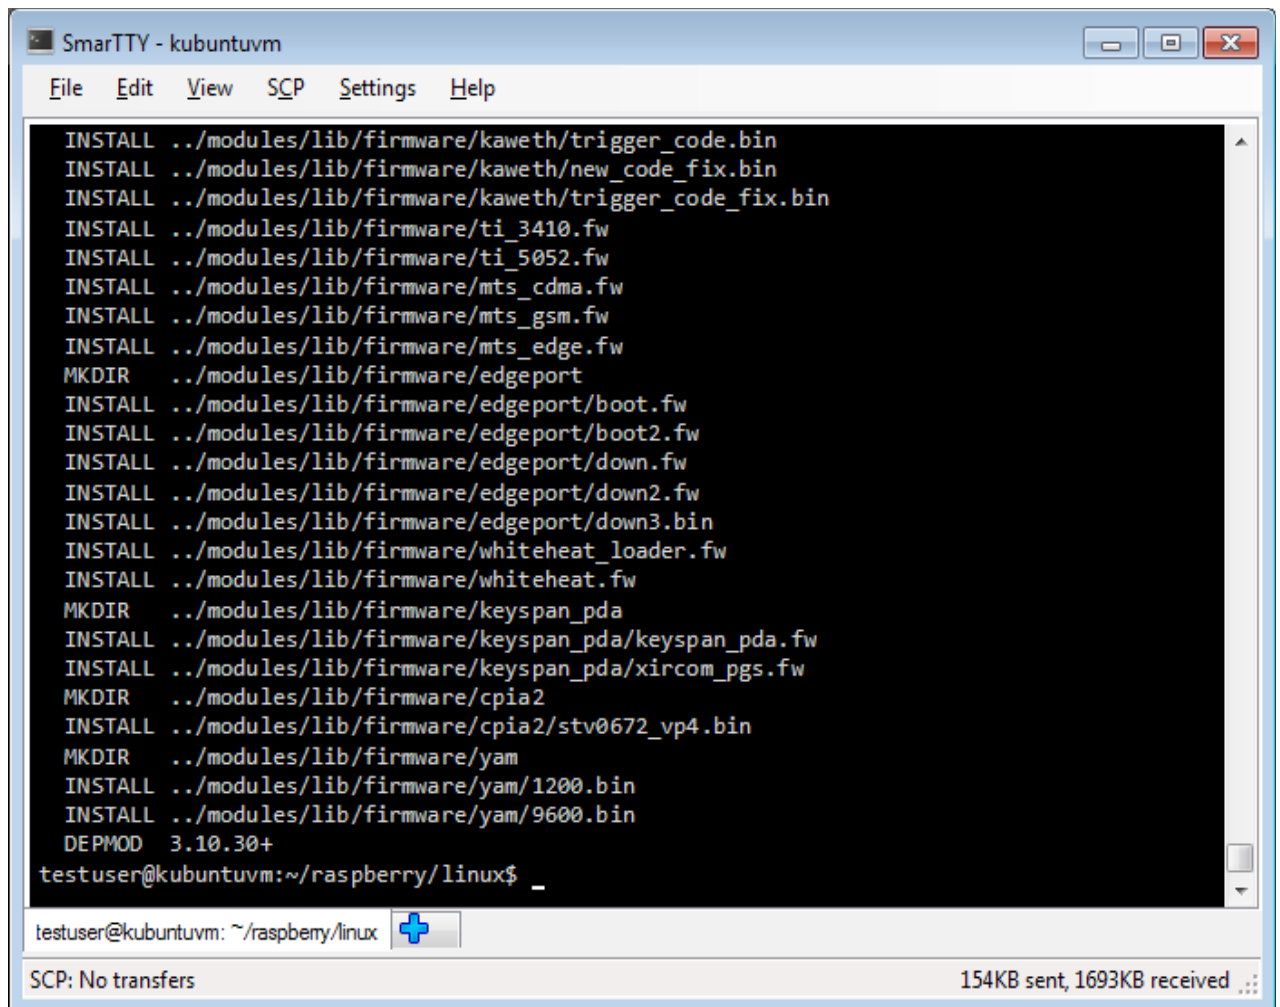

testuser@kubuntuvvm:~/raspberrylinux$ ${CCPREFIX}gdb vmlinux
GNU gdb (crosstool-NG linaro-1.13.1-4.8-2014.01 - Linaro GCC 2013.11) 7.6.1-2013.10

This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=i686-build_pc-linux-gnu --target=arm-linux-gnueabi".
For bug reporting instructions, please see:
<https://bugs.launchpad.net/gcc-linaro>...
Reading symbols from /home/testuser/raspberrylinux/vmlinux...done.
(gdb) print init_uts_ns.name.release
$1 = "3.10.30+", '\000' <repeats 56 times>
(gdb) _

testuser@kubuntuvvm: ~/raspberrylinux
SCP: No transfers 266KB sent, 10113KB received
```

If GDB can display the kernel release string, the kernel has been built with sufficient symbols for kernel debugging.

11. Now that we have verified that the kernel contains the symbols, we will need to generate a directory containing kernel modules that Raspberry PI can load when needed. Run the following command to copy the modules to the './modules' directory:

```
ARCH=arm CROSS_COMPILE=${CCPREFIX} INSTALL_MOD_PATH=../modules
make modules_install
```

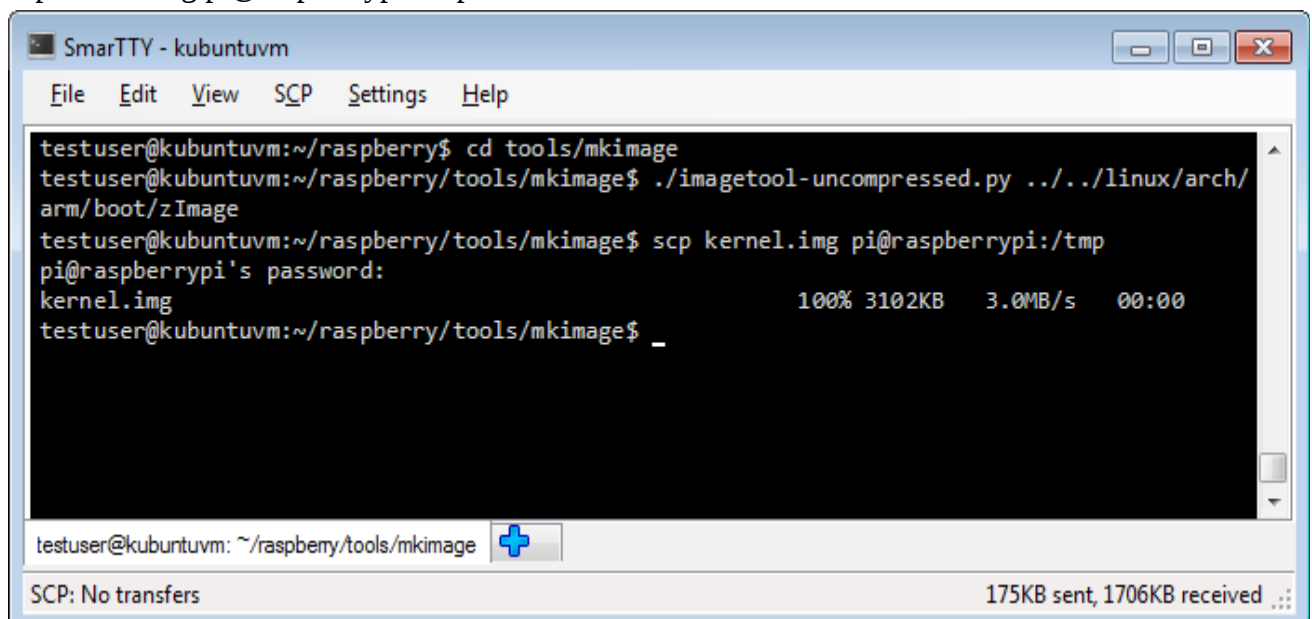

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

INSTALL ../modules/lib/firmware/kaweth/trigger_code.bin
INSTALL ../modules/lib/firmware/kaweth/new_code_fix.bin
INSTALL ../modules/lib/firmware/kaweth/trigger_code_fix.bin

DEPMOD 3.10.30+
testuser@kubuntuvvm:~/raspberrylinux$ _

testuser@kubuntuvvm: ~/raspberrylinux
SCP: No transfers 154KB sent, 1693KB received
```

12. Now we need to upload the new kernel and the new modules to Raspberry PI. First we will create an uncompressed kernel image and upload it to the temporary directory on Raspberry PI. Run the following commands on your build machine:

```
cd <raspberrypi downloads>/tools/mkimage
./imagetool-uncompressed.py ../../linux/arch/arm/boot/zImage
scp kernel.img pi@raspberrypi:/tmp
```

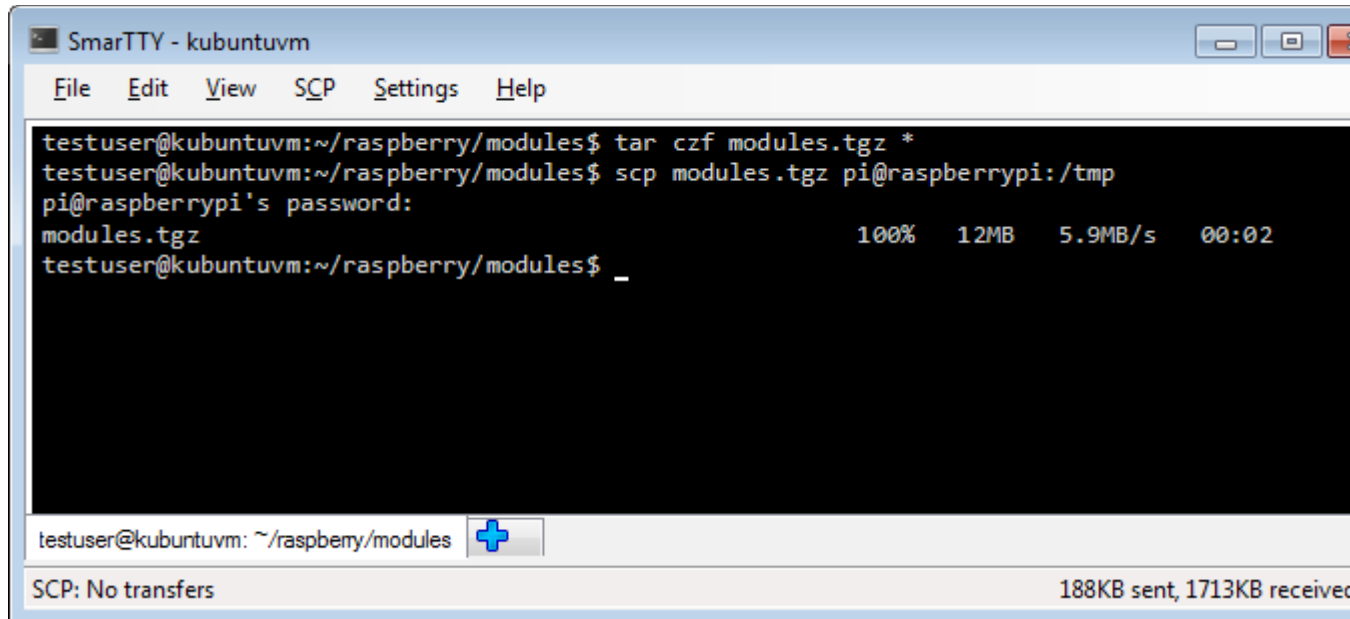

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

testuser@kubuntuvvm:~/raspberrypi$ cd tools/mkimage
testuser@kubuntuvvm:~/raspberrypi/tools/mkimage$ ./imagetool-uncompressed.py ../../linux/arch/arm/boot/zImage
testuser@kubuntuvvm:~/raspberrypi/tools/mkimage$ scp kernel.img pi@raspberrypi:/tmp
pi@raspberrypi's password:
kernel.img 100% 3102KB 3.0MB/s 00:00
testuser@kubuntuvvm:~/raspberrypi/tools/mkimage$ _

testuser@kubuntuvvm: ~/raspberrypi/tools/mkimage
SCP: No transfers 175KB sent, 1706KB received
```

13. Then go to the 'modules' subdirectory we created before, make a tar archive containing the modules and upload it to Raspberry PI:

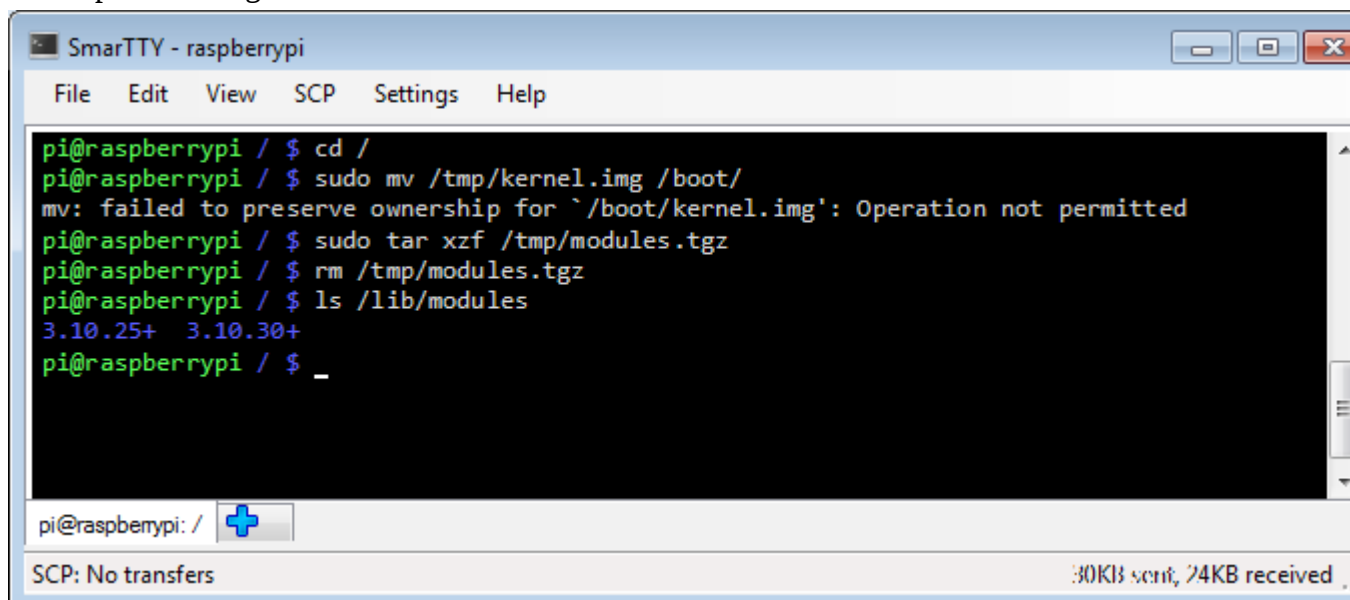

```
cd <raspberrypi downloads>/tools/modules
tar czf modules.tgz *
scp modules.tgz pi@raspberrypi:/tmp
```

The screenshot shows a terminal window titled 'SmarTTY - kubuntuvvm'. The user 'testuser' is in the directory '~ /raspberry/modules'. They run 'tar czf modules.tgz *' to create a tar archive. Then, they run 'scp modules.tgz pi@raspberrypi:/tmp'. The terminal shows the password prompt for 'pi@raspberrypi' and a progress bar for the SCP transfer: 'modules.tgz 100% 12MB 5.9MB/s 00:02'. The window status bar at the bottom indicates 'SCP: No transfers' and '188KB sent, 1713KB received'.

14. Finally we need to install the kernel and the modules. Connect to your Raspberry PI over SSH and run the following commands:

```
cd /
sudo mv /tmp/kernel.img /boot/
sudo tar xzf /tmp/modules.tgz
rm /tmp/modules.tgz
```

The screenshot shows a terminal window titled 'SmarTTY - raspberrypi'. The user 'pi' is at the root directory '/'. They run 'cd /', then 'sudo mv /tmp/kernel.img /boot/'. An error message appears: 'mv: failed to preserve ownership for `/boot/kernel.img': Operation not permitted'. They then run 'sudo tar xzf /tmp/modules.tgz', 'rm /tmp/modules.tgz', and 'ls /lib/modules'. The output of 'ls' shows '3.10.25+' and '3.10.30+'. The window status bar at the bottom indicates 'SCP: No transfers' and '30KB sent, 24KB received'.

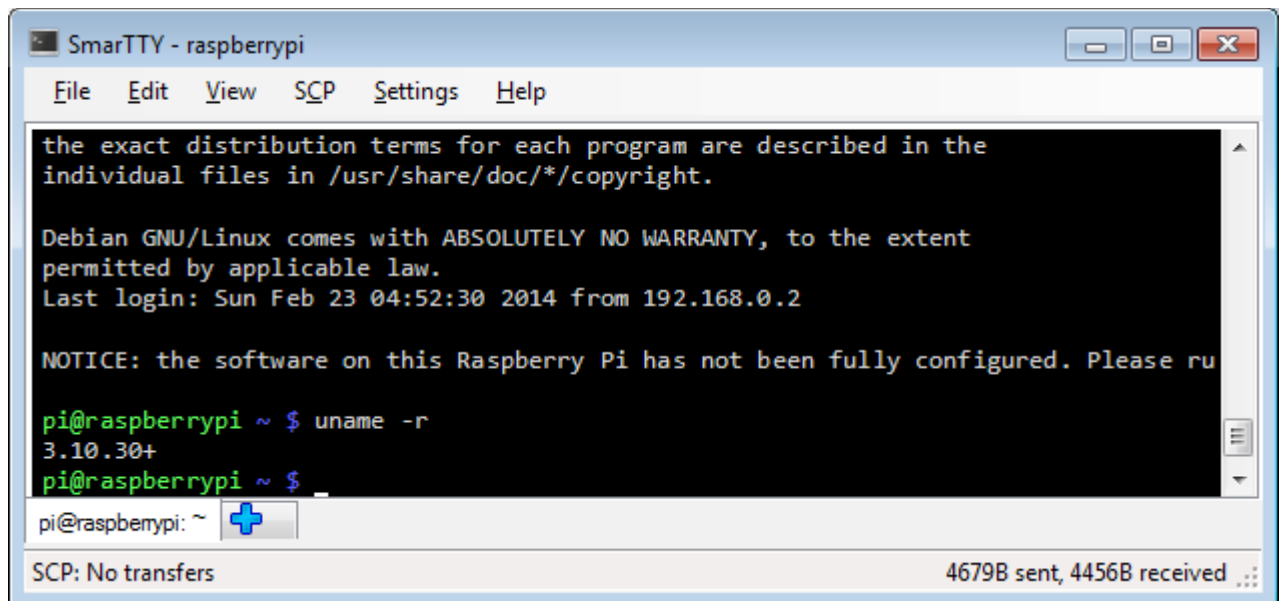

If you now list the contents of /lib/modules you will see that it now also contains the modules for the new kernel.

15. Restart your Raspberry PI to boot the new kernel:

```
sudo shutdown -r now
```

16. Once Raspberry PI boots, connect to it over SSH and run the 'uname -r' command to see the

new kernel release:

```
SmarTTY - raspberrypi
File Edit View SCP Settings Help

the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Debian GNU/Linux comes with ABSOLUTELY NO WARRANTY, to the extent
permitted by applicable law.
Last login: Sun Feb 23 04:52:30 2014 from 192.168.0.2

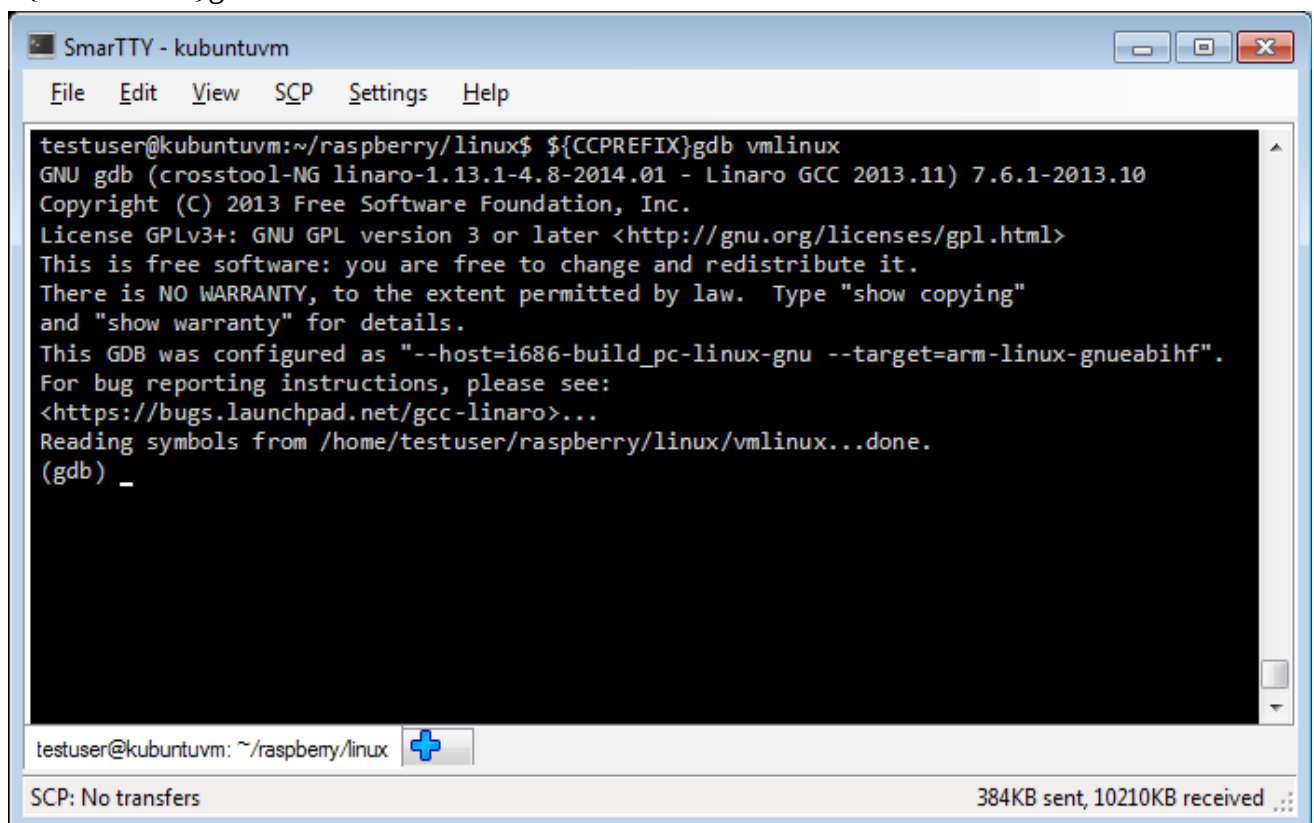

NOTICE: the software on this Raspberry Pi has not been fully configured. Please ru

pi@raspberrypi ~ $ uname -r
3.10.30+
pi@raspberrypi ~ $
pi@raspberrypi: ~ +
SCP: No transfers 4679B sent, 4456B received
```

The release string should match the one we queried before when testing the kernel symbols.

17. Now you should be able to debug your kernel. Follow our [Raspberry PI JTAG setup tutorial](#) if you have not done that already. Once the JTAG connection is established, begin debugging by running the following command on your build machine:

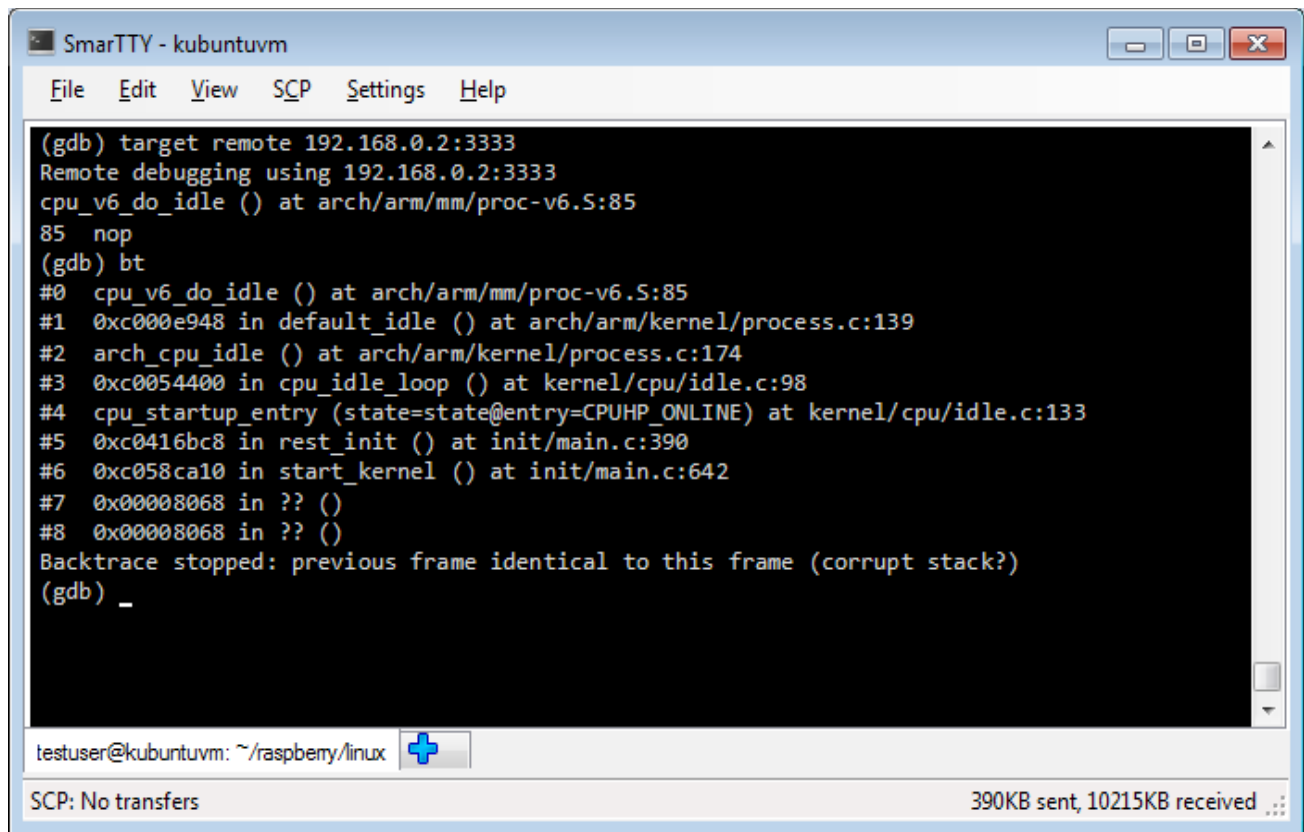

`${CCPREFIX}gdb vmlinux`

```
SmarTTY - kubuntuvvm
File Edit View SCP Settings Help

testuser@kubuntuvvm:~/raspberrylinux$ ${CCPREFIX}gdb vmlinux
GNU gdb (crosstool-NG linaro-1.13.1-4.8-2014.01 - Linaro GCC 2013.11) 7.6.1-2013.10
Copyright (C) 2013 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=i686-build_pc-linux-gnu --target=arm-linux-gnueabi".
For bug reporting instructions, please see:
<https://bugs.launchpad.net/gcc-linaro>...
Reading symbols from /home/testuser/raspberrylinux/vmlinux...done.
(gdb) _
testuser@kubuntuvvm: ~/raspberrylinux +
SCP: No transfers 384KB sent, 10210KB received
```

18. Connect to OpenOCD by running the "target remote <OpenOCD host>:3333" command and display the stack trace using the [bt](#) command:

The screenshot shows a SmarTTY terminal window titled "SmarTTY - kubuntuvvm". The menu bar includes File, Edit, View, SCP, Settings, and Help. The terminal output shows a GDB session where a target is connected to 192.168.0.2:3333. The current function being debugged is `cpu_v6_do_idle ()` at `arch/arm/mm/proc-v6.S:85`. The instruction at this location is `85 nop`. The user enters `(gdb) bt`, and the backtrace shows the following stack frames:

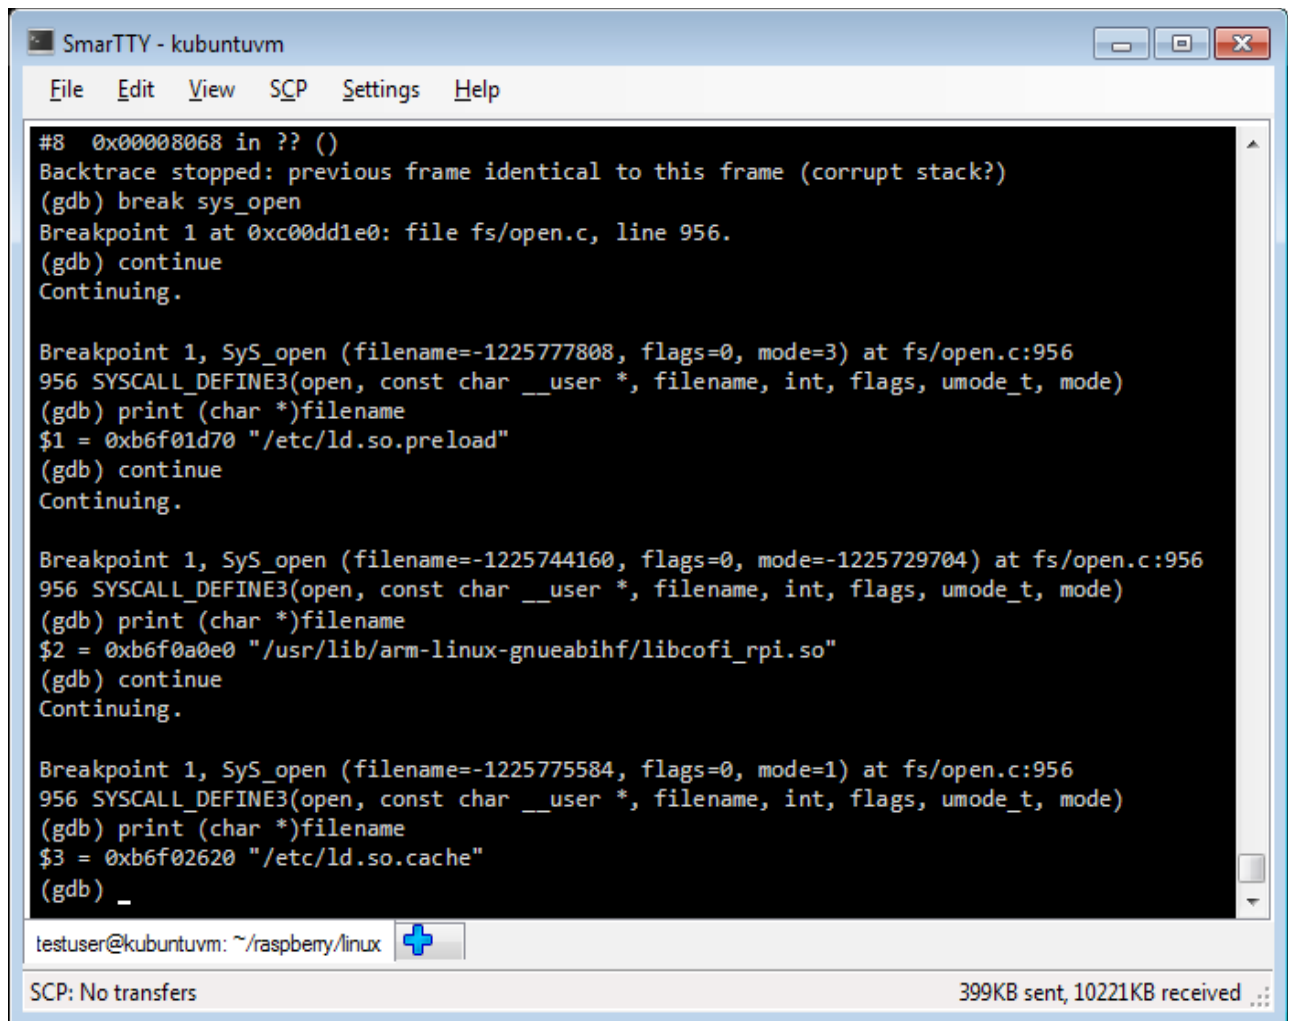

- #0 `cpu_v6_do_idle ()` at `arch/arm/mm/proc-v6.S:85`
- #1 `0xc000e948 in default_idle ()` at `arch/arm/kernel/process.c:139`
- #2 `arch_cpu_idle ()` at `arch/arm/kernel/process.c:174`
- #3 `0xc0054400 in cpu_idle_loop ()` at `kernel/cpu/idle.c:98`
- #4 `cpu_startup_entry (state=state@entry=CPUHP_ONLINE)` at `kernel/cpu/idle.c:133`
- #5 `0xc0416bc8 in rest_init ()` at `init/main.c:390`
- #6 `0xc058ca10 in start_kernel ()` at `init/main.c:642`
- #7 `0x00008068 in ?? ()`
- #8 `0x00008068 in ?? ()`

The backtrace stops with the message: "Backtrace stopped: previous frame identical to this frame (corrupt stack?)". The prompt `(gdb) _` is shown. At the bottom of the window, the status bar displays "testuser@kubuntuvvm: ~/raspberrylinux" with a plus icon, "SCP: No transfers", and "390KB sent, 10215KB received".

19. Now we'll test breakpoint support by setting a breakpoint at the **sys_open()** function:

`break sys_open continue`

20. Now go to the Raspberry PI SSH window and run `'ls /tmp'` command. The **sys_open** breakpoint will be triggered. Run `"print (char *)filename"` to see the name of the file being opened:

```
#8 0x00008068 in ?? ()
Backtrace stopped: previous frame identical to this frame (corrupt stack?)
(gdb) break sys_open
Breakpoint 1 at 0xc00dd1e0: file fs/open.c, line 956.
